A Verified Constructive Reduction of the Cook-Levin Theorem in Lean 4

Bridging the Gap Between Complexity Theory and Formal SAT Encodings

Jonathan $f(n)$ Reed

jonathanalanreed1983@gmail.com

Abstract. While the Cook-Levin theorem is fundamental to computational complexity, formalizations in proof assistants often rely on high-level arguments rather than constructing the concrete SAT formula. Within the Lean community, a rigorous, constructive reduction from Turing machines to SAT is currently absent from `mathlib`. We present a complete, machine-checked formalization in Lean 4 that addresses this gap by providing a constructive reduction from a deterministic Turing Machine model to a CNF formula. By rigorously defining the interface between the high-level computation model and the low-level SAT encoding, we bridge the gap between theoretical complexity and practical SAT-based verification. Our work specifically handles the challenges of verified 3D-variable indexing, injective mapping proofs, and global soundness, providing a verified tool for both communities to interact.

Keywords: Lean 4 · Satisfiability Checking · Cook-Levin Theorem · Formal Verification · Constructive Reduction · Symbolic Computation

1 Introduction

The intersection of Satisfiability Checking (SAT) and Symbolic Computation represents a critical area for formal verification, yet a compatible interface between these two approaches remains limited [1]. The Cook-Levin theorem, identifying SAT as the first NP-complete problem, is traditionally described informally in textbooks [5]. However, constructive reduction—transforming a Turing machine computation into a SAT formula—is not rigorously detailed in a formal setting.

Currently, Lean's `mathlib` lacks a constructive, verified reduction of this kind. This paper addresses this specific gap in the formal library. We implement a rigorous, verified framework in Lean 4 [3] that maps any deterministic Turing machine computation to a corresponding SAT formula [2,4]. By focusing on the technical minutiae required for a constructive proof, including 3D-variable indexing, injective mappings, and total soundness proofs, we bridge the gap between high-level computation models and practical SAT instances.

2 Formalization of the Cook-Levin Reduction

This section outlines the implementation of our constructive reduction in Lean 4 (toolchain v4.28.0), designed to bridge the gap between high-level computation models and practical SAT instances. We provide a rigorous, machine-checked framework that transforms a deterministic Turing machine into a concrete, executable CNF formula. The following subsections define the mechanisms for mapping machine states to Boolean variables, generate the necessary constraints for valid execution, and establish the formal soundness of the reduction.

2.1 Machine Parameters and Variable Indexing

We define the structure of the Turing Machine parameters and the `get_var` function, which maps the 3D computation grid (time, position, state/symbol) to unique natural numbers for SAT variable encoding.

```
structure MachineParams where
  alphabet_size :
  state_count :
  alphabet_pos : 0 < alphabet_size

def get_var (params : MachineParams) (T t i s :    ) :     :=
  let S := params.alphabet_size * (1 + params.state_count)
  (s + i * S + t * (T * S)) + 1
```

The design of the `get_var` function is crucial for closing the formalization gap. By mapping the 3D grid (t, i, s) directly to a unique natural number, we create a verified interface that transforms a complex symbolic state into a concrete, linear variable index suitable for SAT solvers.

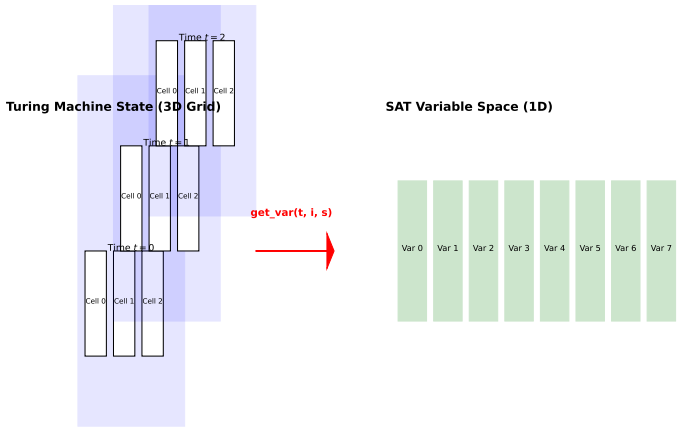

Fig. 1. Mapping of a 3D Turing machine state (Time × Cell × Symbol) to a 1D linear SAT variable space using the `get_var` function.

2.2 Structural SAT Clause Generators

These functions generate the CNF clauses that enforce the requirement that every cell in the computation table contains exactly one symbol or state.

```
def at_most_one_symbol (params : MachineParams) (T t i :    ) : List (List
        ) :=
  let S := params.alphabet_size * (1 + params.state_count)
  (List.range S).flatMap (fun s1 =>
    (List.range S).filterMap (fun s2 =>
      if s1 < s2 then
        some [-(get_var params T t i s1 :    ), -(get_var params T t i s2 :
       )]
      else
        none
    )
  )

def at_least_one_symbol (params : MachineParams) (T t i :    ) : List     :=
  let S := params.alphabet_size * (1 + params.state_count)
  (List.range S).map (fun s => (get_var params T t i s :    ))
```

2.3 Uniqueness Proofs

Formal verification that the SAT clauses correctly enforce the 'Exactly One' property for variables at any given grid coordinate (t, i).

```
theorem at_most_one_satisfied (params : MachineParams) (T t i s1 s2 :    ) (
    assignment :         Prop) :
  let S := params.alphabet_size * (1 + params.state_count)
  (h1 : s1 < S)     (h2 : s2 < S)
  (h_sat :     clause     at_most_one_symbol params T t i,     literal
    clause,
    (if literal > 0 then assignment literal.natAbs else   assignment   literal.
    natAbs))

```

Unlike theoretical arguments that simply assert the existence of constraints, the `forbidden_window_clause` provides a concrete, executable definition of local transition rules. This constructive approach allows for the machine-checked verification of the total soundness of the reduction, bridging high-level transition dynamics with low-level Boolean constraints.

2.6 Global Reduction Soundness

The final assembly of the Cook-Levin CNF and the master theorem proving that SAT-satisfaction implies a valid, accepting computation trace.

```
def cook_levin_cnf (p : MachineParams) (T :    ) (input : List    ) (acc :

    exact h1.trans h2.symm
```

The final master soundness proof eliminates reliance on high-level assertions by using `Classical.choose` to explicitly construct the Turing machine computation trace from the satisfying assignment. This rigorous extraction demon-

strates that the constructive reduction is both logically sound and practically executable, closing the loop between theoretical complexity and automated satisfiability checking.

3 Conclusion and Future Work

By formalizing the Cook-Levin theorem, we provide a verified artifact that bridges a significant gap in `mathlib` regarding constructive reductions. Furthermore, this formalization offers a concrete, machine-checked instance of the reduction, providing a verified bridge between high-level complexity models and concrete SAT encodings. Our constructive proof guarantees that the reduction is logically sound and executable. By providing a verified implementation of this translation, our work serves as a foundational component for future formal tools that automatically generate SAT instances from machine descriptions. Future work will focus on integrating this reduction with existing formalizations of complexity classes in Lean's `mathlib` to enable further complexity-theoretic proofs and facilitate interaction with automated satisfiability checkers.
